A hard sweep occurs when one or a small number of haplotypes present in standing genetic variation in this case, in the ancestral oceanic pool is selected to high frequency in this case, in the newly established freshwater populations. Figure 8. View on PubMed.

We can draw further evolutionary inferences by focusing on the patterns of divergence among populations. Table 1. Previous QTL mapping analyses, using crosses between oceanic and freshwater stickleback populations or among freshwater ecotypes, uncovered genomic regions co-segregating with various morphological traits, including the aforementioned presence or absence of lateral plate or pelvic armor elements and aspects of head and body geometry [91][]. Exclusive Interview with Dave Marchetti. For additional information, see the Global Shipping Program terms and conditions. We used a novel high-throughput Steve the Stickleback genotyping approach to produce the first high density genome-wide scans of threespine stickleback populations and identified several genomic regions indicative of both divergent and balancing selection. Candidate loci for adaptation to freshwater We identified a list of candidate genes within peaks of parallel divergence among stickleback populations that may be important for adaptation to freshwater.
